

Computational Models

For human behavior
representation
Interchange Standard

Avelino J. Gonzalez
Jose Castro
Robert Franceschini
University of Central Florida

Advantages of Common Interchange System

- ◆ Knowledge can be captured and represented only once.
- ◆ Knowledge core is common - only the representation varies.
- ◆ Cumulative base of knowledge can be built over time.

Human Behavior Knowledge

- ◆ Temporal considerations of great importance - short time scale
- ◆ Highly individualized
- ◆ Highly dependent on context
- ◆ Grows with experience
- ◆ Not completely understood

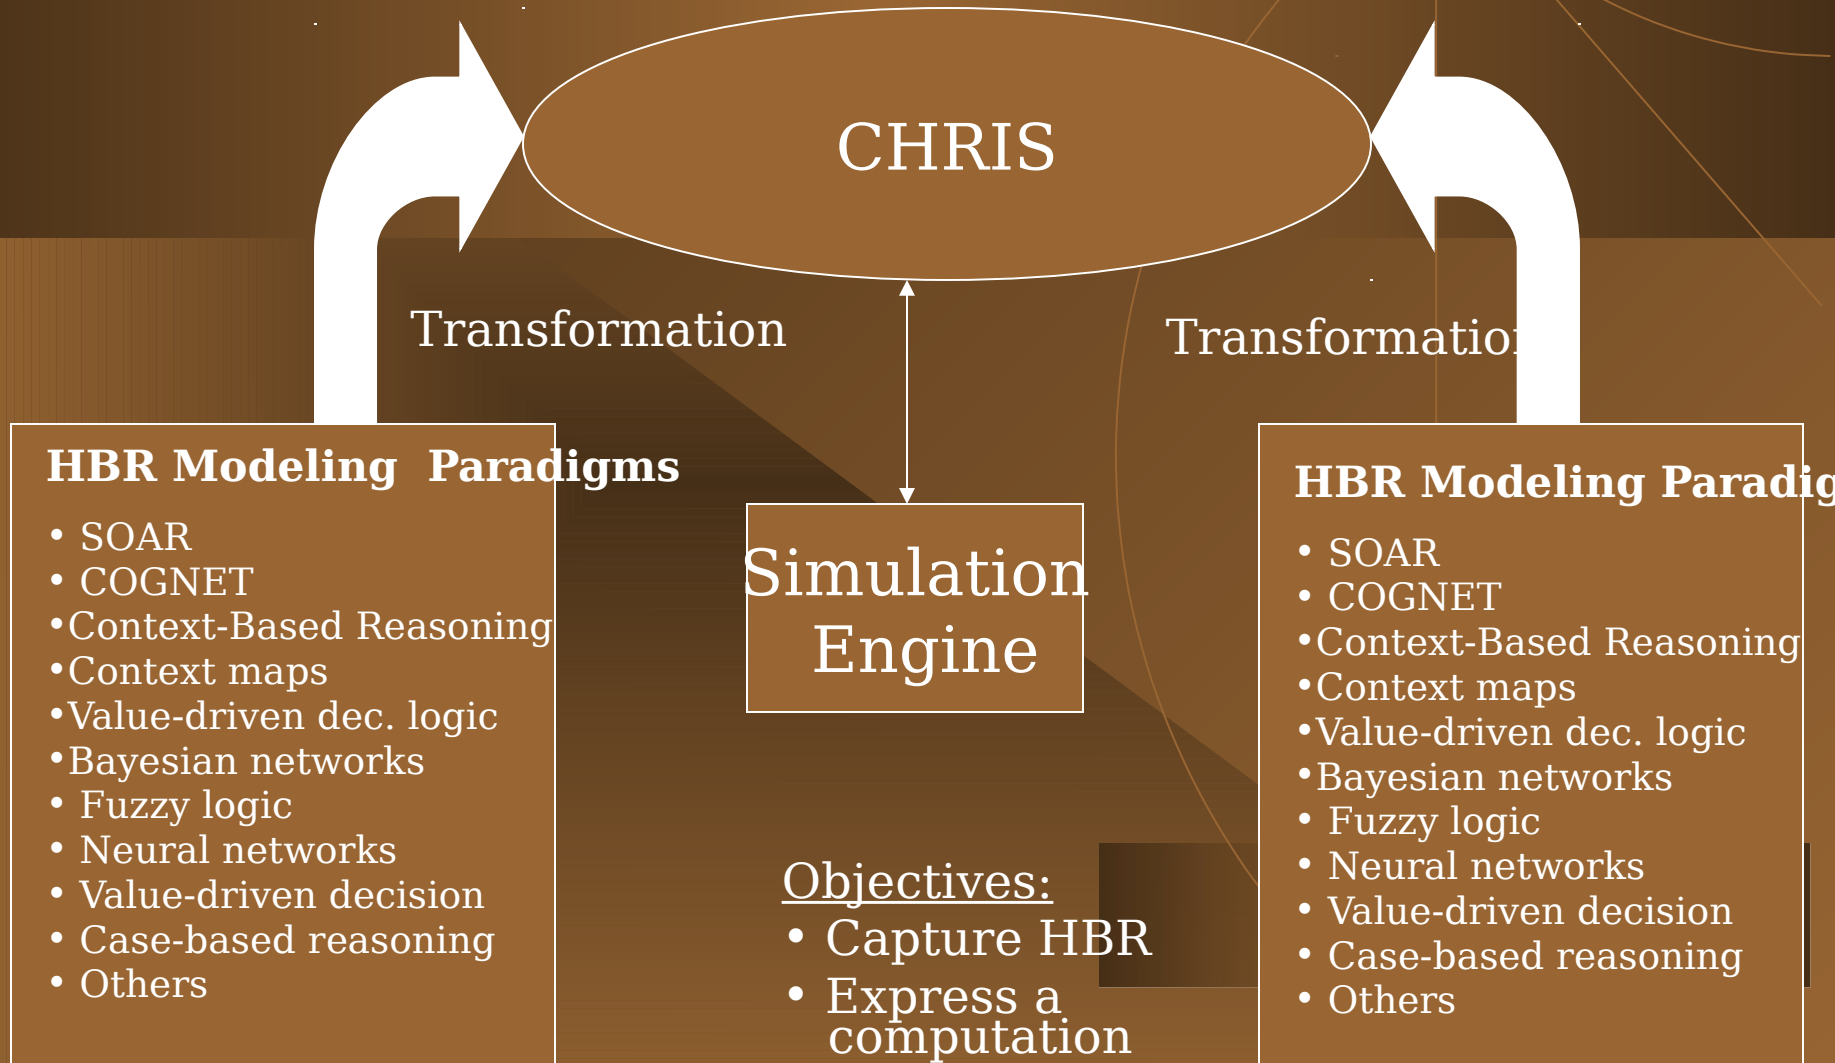

Terrain Data - SEDRIS

- ◆ Temporal considerations of less importance
- ◆ Knowledge not involved
- ◆ Commonly perceived
- ◆ Does not grow with experience
- ◆ Not context dependent
- ◆ Largely understood for today's application

Notional CHRIS

Common Human Behavior Interchange System Requirements

- ◆ Must select simple yet powerful paradigm as basis.
- ◆ Paradigm can grow without invalidating prior knowledge representations.
- ◆ Existing representations must be transformable to paradigms.
- ◆ File format must be developed.

Turing Machine

- ◆ Most powerful computational paradigm
- ◆ Reads and writes on an infinite tape memory with symbols
- ◆ It has two functions, a state transition function and a tape action function
 - ◆ tape action can be:
 - ◆ move left
 - ◆ move right
 - ◆ write symbol

Turing Machines

- ◆ Can recognize anything computable
 - ◆ The most general paradigm
 - ◆ Generality hinders applicability
 - ◆ Of mathematical/theoretical interest only
 - ◆ Have never been implemented for actual computer use

Proposed Paradigm

- ◆ Finite State Machine

Finite State Machine Characteristics

- ◆ Mathematical Abstraction of the form
- ◆ $\text{FSM} \equiv (\Sigma, Q, R, F, \delta)$
 - ◆ Σ possible events
 - ◆ Q a set of states
 - ◆ R a start state
 - ◆ $F \subseteq Q$, set of accepting states
 - ◆ $\delta : Q \times \Sigma \rightarrow Q$, a state transition function

Properties of FSM

- ◆ FSM recognize regular languages (languages denoted by regular expressions):
 - ◆ $\{a|b\}^*c^+$
 - ◆ Can be used, and are frequently used for computation in:
 - ◆ Compilers
 - ◆ Simulation systems
 - ◆ Text search systems

FSM Characteristics - Advantages

- ◆ Mathematically sound and well-studied abstraction
- ◆ Can be represented as Graphs or Tables
- ◆ Easy to implement
- ◆ Make for efficient computer systems
- ◆ Represent behavior (action-reaction) naturally

FSM Characteristics - Advantages (Cont.)

- ◆ Already used in several CGF applications (e.g., ModSAF CCTT and others)
- ◆ Several extensions exist that make them powerful representational paradigms

FSM Characteristics - Disadvantages

- ◆ Do not have unlimited memory, therefore, cannot solve certain kinds of problems
- ◆ Encourage a “behaviorist” model and not a “cognitive” model, (emphasize action-reaction and not internal representation)
- ◆ Limited complexity of problems able to solve.

FSM Characteristics - Disadvantages (Cont.)

- ◆ Are not by themselves a
Interchange format.

Variations of Finite State Machines

- ◆ There are variations of finite state machines that address these disadvantages
 - ◆ Non-deterministic FSM
 - ◆ Push-down Automata
 - ◆ Hybrid Automata
 - ◆ Cellular Automata
 - ◆ Fuzzy Automata
 - ◆ Timed Automata
 - ◆ Tree Automata

Non-deterministic Finite State Machines (NFSM)

- ◆ Automata whose state transition function δ evaluates to set of possible states.
- ◆ Has same computing power as FSM \implies no computational advantage
- ◆ Can be a more “natural” representation

Push Down Automata

- ◆ An FSM with a stack - permits push and pop from memory.
 - ◆ The state transition function δ depends on the value on top of the stack and on the state
 - ◆ Function added to define the push and pop operations
 - ◆ $(\text{state}, \text{TOS}, \text{input}) \Rightarrow \text{action}(\text{TOS})$

Pushdown Automata

- ◆ Recognize nested contexts
- ◆ Are more powerful than FSM (If a FSM exists to recognize situation L , then a Pushdown automata also exists)
- ◆ Used mostly in computer language compilers

Hybrid Automata

- Combines time-driven and event driven dynamics.
- ◆ A generalization of a finite-state automaton, equipped with a set of variables
- Is able to model discrete events and continuous activities, governed by a set of differential equations.
- Provides a modeling paradigm for hybrid systems
- Described by a finite set of real-valued variables and a labeled multi-graph (V,E)

Hybrid Automata

Formally: $H = (X, V, E, \text{syn}, \text{act}, \text{inv})$

- ◆ Continuous variable set $X = (x_1, x_2, \dots, x_n)$
Valuation of H $s = (x_1 = a_1, x_2 = a_2, \dots, x_n = a_n)$

- Control locations V

A state of the automaton is a pair (v, s) . Where $v \in V$ is the location and $s \in R^n$ is a valuation

Hybrid Automata

- ◆ Finite set of transitions \mathbf{E}
- ◆ A transition $e = (v, a, u, v')$
- ◆ Source location $v \in V$
- ◆ Target location $v' \in V$
- ◆ Synchronization label $a \in \text{syn}$
- ◆ Transition relation $u \subseteq S^2$

Hybrid Automata

- Synchronization labels **syn**, parallel composition of two automata.
- Activities **act**, assigns to each location $v \in V$ a set of activities
- A function invariant **inv**, assigns to each location $v \in V$ an invariant $inv(v) \subseteq S$

Hybrid System

- ◆ A node in the automaton is a discrete state combined with the continuous dynamics connected to that state.

SHIFT

- ◆ The name SHIFT is a permutation of HSTIF (Hybrid System Tool Interchange Format)
- ◆ Description language for dynamic networks of hybrid system.
- ◆ System consists of components, which can be created, interconnected and destroyed as the system evolves in time.
- ◆ Components exhibit hybrid behavior, consisting of continuous-time phases separated by discrete event transitions.

Dymola

- **Dynamic Modeling Language**
- Object-oriented modeling
- ◆ Reuse of library models
- ◆ Graphical model composition
- ◆ Symbolic equation processing
- ◆ Efficient hybrid simulation including 3-D animation
- ◆ Manipulate Hybrid Models

Cellular Automata

- ◆ Unidimensional or bidimensional grid of cells
- ◆ Each one of the cells is a simple automaton
- ◆ The automata's input is the state of the neighboring cells
- ◆ Used in biological and population growth mathematical studies
- ◆ Turing equivalent

Comparison

- ◆ $\text{FSM} \equiv \text{NFSM} < \text{Pushdown Automata} < \text{Turing Machines}$
- ◆ FSM used most of all
- ◆ NFSM used for notation
- ◆ Pushdown automata used in compilers only
- ◆ Turing machines never used

FSM for Human Behavior

- ◆ Mathematically sound and proven
- ◆ Already used in many systems
- ◆ Simple and efficient
- ◆ Even though not a file format in itself, can be easily stored and transmitted
- ◆ A working core of FSM representation of HB guaranteed (already exists).

FSM for Human Behavior

- ◆ Information in other knowledge forms can be transformed to FSM
 - ◆ Transformation from case-based and context-based systems is straight forward for extended automata
 - ◆ Transformation from rule-based paradigms is also direct
 - ◆ Connectionist Models?

FSM and Neural Networks

- ◆ ANN's used for automatic knowledge extraction
- ◆ Can learn from examples
- ◆ Recurrent neural networks (RNN) easily mapped to FSM and vice-versa
 - ◆ RNN have naturally unbounded input lengths.

Suggested Approach

- ◆ Feasibility Study - using Finite State Automata extensions as the interchange standard.
- ◆ Study feasibility of Transforming between the several paradigms into the FSM standard.
- ◆ Develop prototype system to evaluate effectiveness.
